## The Recursive Process

Recursive solutions involve two major parts:

- Base case(s), the problem is simple enough to be solved directly
- Recursive case(s). A recursive case has three components:
- Divide the problem into one or more simpler or smaller parts
- Invoke the function (recursively) on each part, and
- Combine the solutions of the parts into a solution for the problem.

## Why learn recursion?

- Recursive data is all around us!
- Take CS61B (data structures), CS70 (discrete math), CS164 (Programming Languages), Data 101 (Data Eng) for more examples where you'll encounter recursion
- Trees (post-midterm) and Graphs are structures which are recursive in nature.
- E.g. A social network is a graph of friends with connections to other friends, with connections to other friends.
- Analyzing "chains" of data, can benefit from recursion
- Next Lecture: Problems that "branch" out:
- generating subsets and permutations
- calculating Fibonacci numbers

## Computational Structures in Data Science

## Palindromes

©(1)(ㅇ

## Learning Objectives

- Compare Recursion and Iteration to each other
- Translate some simple functions from one method to another
- Write a recursive function
- Understand the base case and a recursive case

## Palindromes

- Palindromes are the same word forwards and backwards.
-Python has some tricks, but how could we build this?
- palindrome = lambda w: w == w[::-1]
- [: : -1 ] is a slicing shortcut [0:len(w):-1] to reverse items.
- Let's write Reverse:

```
def reverse_while(s):
    """
    >>> reverse_while('hello')
    'olleh'
    """
    result = ''
    while s:
        first = s[0]
        s = s[1:] # remove the first letter
        result = first + result
    return result
```

```
def reverse(s):
    result = ''
    for letter in s:
        result = letter + result
```

    return result

-https://czechtheworld.com/best-palindromes/\#palindrome-words

## Writing Reverse Recursively

def reverse(s): if not s: return '' return 'TODO'
def palindrome(word):
return word == reverse(word)

How should reverse work?

- Our algorithm in words:
- Take the first letter, put it at the end
- The beginning of the string is the reverse of the rest.

$$
\begin{aligned}
& \text { reverse('ABC') } \\
& \rightarrow \text { reverse('BC') + 'A' } \\
& \rightarrow \text { reverse('C') + 'B' + 'A } \\
& \rightarrow \text { 'C' + 'B' + 'A } \\
& \rightarrow \text { 'CBA' }
\end{aligned}
$$

## reverse recursive

def reverse(s):
if not $s$ :
return ''
return $\quad$ Recursive Case
def palindrome(word):
return word $==$ reverse(word)

## Palindrome - Alternative Approaches

- Compare first / last letters, working our way towards the middle
- Base Case?
- What is the smallest word that is a palindrome?
-A 1-letter word!
- A 0 letter word? Maybe?
- We can have a recursive case:
- If the first and last letter are the same, check the "inner word"
- If they're not $\rightarrow$ return False

## Computational Structures in Data Science

## Summing Numbers

Combining Return Values

Berkeley

## Iteration vs Recursion: Sum Numbers

While loop:

## def $\operatorname{sum}(n)$ :

total $=0$
i = 0
while $i<n:$
i += 1
total += i
return total

For loop:
def $\operatorname{sum}(n):$
total $=0$
for $i$ in range ( $0, \mathrm{n}+1$ ): total += i
return total

## Recursively Sum Number

- What is the base case?
-What is the smallest number that we can sum to?
- If so, what is the result?

```
def sum(n):
    if n == 0:
        return 0
```

## Recursively Sum Numbers

Recursion:
def $\operatorname{sum}(n):$
if $n==0:$
return 0
return $\mathrm{n}+\operatorname{sum}(\mathrm{n}-1)$

## Iteration vs Recursion: Cheating!

Sometimes it's best to just use a formula! But that's not always the point. ©
def $\operatorname{sum}(n):$ return (n * (n + 1)) / 2

## Review: Functions

def <function name> (<argument list>) :

- Generalizes an expression or set of statements to apply to lots of instances of the problem
- A function should do one thing well

## How does it work?

-Each recursive call gets its own local variables
-Just like any other function call

- Computes its result (possibly using additional calls)
- Just like any other function call
- Returns its result and returns control to its caller
- Just like any other function call
-The function that is called happens to be itself
- Called on a simpler problem
- Eventually stops on the simple base case

## Computational Structures in Data Science

## Recursion With Lists

Berkeley

## Another Example - Finding a Minimum

```
indexing an element of a sequence
```

```
def first(s):
    """Return thirst element in a sequence."""
    return s[0]
def rest(s):
    """Return all elements in a sequence after the first"""
    return s[1:]
                                    Slicing a sequence of elements
def min_r(s):
    """Return minimum value in a sequence."""
    if Base Case
    else:
                    Recursive Case
```

- Recursion over sequence length

## Computational Structures in Data Science

## Understanding Order of Execution

Berkeley

## Recall: Iteration

## Recursion Key concepts - by example

## In words

-The sum of no numbers is zero
-The sum of $1^{2}$ through $n^{2}$ is the

- sum of $1^{2}$ through ( $\left.\mathrm{n}-1\right)^{2}$
- plus $\mathrm{n}^{2}$

$$
\begin{aligned}
& \text { def sum_of_squares }(n): \\
& \text { if } \mathrm{n}<1: \\
& \quad \text { return } 0 \\
& \text { else: } \\
& \quad \text { return sum_of_squares }(n-1)+n \star \star 2
\end{aligned}
$$

## Why does it work

```
sum_of_squares(3)
# sum_of_squares(3) => sum_of_squares(2) + 3**2
# => sum_of_squares(1) + 2**2 + 3**2
# => sum_of_squares(0) + 1**2 + 2**2 + 3**2
# => 0 + 1**2 + 2**2 + 3**2 = 14
```

## Questions

-In what order do we sum the squares ?
-How does this compare to iterative approach ?

```
def sum_of_squares(n):
    accum = 0
    for i in range(1,n+1):
        accum = accum + i*i
    return accum
```

```
def sum_of_squares(n):
    if n < 1:
        return 0
    else:
        return sum_of_squares(n-1) + n**2
```

```
def sum_of_squares(n):
```

def sum_of_squares(n):
if n < 1:
if n < 1:
return 0
return 0
else:
else:
return n**2 + sum_of_squares(n-1)

```
        return n**2 + sum_of_squares(n-1)
```

## Trust ...

-The recursive "leap of faith" works as long as we hit the base case eventually
-What happens if we don't?

## Recursion (unwanted)

## Why Recursion?

-"After Abstraction, Recursion is probably the $2^{\text {nd }}$ biggest idea in this course"
-"It's tremendously useful when the problem is selfsimilar"

- "It's no more powerful than iteration, but often leads to more concise \& better code"
."It's more 'mathematical"'
-"It embodies the beauty and joy of computing"
-...

- Recursive structures exist (sometimes hidden) in nature and therefore in data!
- It's mentally and sometimes computationally more efficient to process recursive structures using recursion.
