1 Lambda expressions

Lambda expressions are one-line functions that specify two things: the parameters and the return expression.

A lambda expression that takes in no arguments and returns 8:

\[
\text{lambda: } \lambda \quad 8 \quad \text{return value}
\]

A lambda expression that takes two arguments and returns their product:

\[
\text{lambda } x, y : x * y \quad \text{parameters} \quad \text{return expression}
\]

Unlike functions created by a def statement, the function object that a lambda expression creates has no intrinsic name and is not bound to any variable. In fact, nothing changes in the current environment when we evaluate a lambda expression unless we do something with this expression, such as assign it to a variable or pass it as an argument to a higher order function.
1. What would Python print?

```python
>>> a = lambda: 5
>>> a()

Solution:
5

>>> a(5)

Solution:
TypeError: <lambda>() takes 0 positional arguments but 1 was given

>>> b = lambda: lambda x: 3
>>> b()(15)

Solution:
3

>>> c = lambda x, y: x + y
>>> c(4, 5)

Solution:
9

>>> d = lambda x: lambda y: x * y
>>> d(3)

Solution:
<function ...>

>>> d(3)(3)

Solution:
9

>>> e = d(2)
>>> e(5)
```
>>> f = lambda: print(1)

Solution:
1

>>> g = f()

Solution:
1
2 Environment Diagrams

1. Draw the environment diagram for evaluating the following code

```python
def mystery_a(lst):
    def mystery_b(color, count):
        lst.extend([color] * count)
    return mystery_b

colors = ["purple", "pink", "brown"]
f = mystery_a(colors)
f("red", 3)
f("blue", 1)
```

Solution: python tutor link

2. If on line 2 and line 4, we replace `mystery_b` with `mystery_a`, what will change in the environment diagram, if anything?

Solution: Only the name of frame 2 would change to `mystery_a`. Nothing else would change, as `mystery_a` would just be a new variable defined in the scope of the f1 frame and would point to the same function object as before, the function object defined on line 2.

3. If on line 3, we change `lst.extend([color] * count)` to `lst.append([color] * count)`, what will change, if anything?

Solution: The list `lst` would grow in length by 1 element, where that one new element would be a list of length ‘count’ and every item in the list would have value equal to `color`.

4. Draw the environment diagram for evaluating the following code

```python
def ross(geller, num):
    return geller(monica(num))

def monica(num):
    if num >= 2:
        return tup[0]
    return tup[num]

f = lambda x: x[-1] == "a"
tup = ("hola", "there")
rachel = ross(f, 5)
```

Solution: Solution: [python tutor link](#)
5. Draw the environment diagram for evaluating the following code

```python
def anna(olaf):
    return lambda a, b: olaf or [a] * b

hans = [1]
elsa = anna(hans.append(4))
kristoff = elsa(3, 4)
```

**Solution:** Solution: https://tinyurl.com/14zjl83t
Dictionaries are data structures which map keys to values. Dictionaries in Python are unordered, unlike real-world dictionaries — in other words, key-value pairs are not arranged in the dictionary in any particular order. Let’s look at an example:

```python
>>> pokemon = {'pikachu': 25, 'dragonair': 148, 'mew': 151}
>>> pokemon['pikachu']
25
>>> pokemon['jolteon'] = 135
>>> pokemon
{'jolteon': 135, 'pikachu': 25, 'dragonair': 148, 'mew': 151}
>>> pokemon['ditto'] = 25
>>> pokemon
{'jolteon': 135, 'pikachu': 25, 'dragonair': 148, 'ditto': 25, 'mew': 151}
```

The keys of a dictionary can be any immutable value, such as numbers, strings, and tuples.\(^1\) Dictionaries themselves are mutable; we can add, remove, and change entries after creation. There is only one value per key, however — if we assign a new value to the same key, it overrides any previous value which might have existed.

To access the value of dictionary at key, use the syntax `dictionary[key]`.

Element selection and reassignment work similarly to sequences, except the square brackets contain the key, not an index.

- To add `val` corresponding to `key` or to replace the current value of `key` with `val`:
  
  ```python
dictionary[key] = val
  ```

- To iterate over a dictionary’s keys:
  ```python
  for key in dictionary: #OR for key in dictionary.keys()
      do_stuff()
  ```

- To iterate over a dictionary’s values:
  ```python
  for value in dictionary.values():
      do_stuff()
  ```

- To iterate over a dictionary’s keys and values:
  ```python
  for key, value in dictionary.items():
      do_stuff()
  ```

- To remove an entry in a dictionary:
  ```python
  del dictionary[key]
  ```

- To get the value corresponding to `key` and remove the entry:

\(^1\)To be exact, keys must be hashable, which is out of scope for this course. This means that some mutable objects, such as classes, can be used as dictionary keys.
3.1 Questions

1. What would Python display?
   ```
   >>> pokemon
   {'jolteon': 135, 'pikachu': 25, 'dragonair': 148, 'ditto': 25, 'mew': 151}
   >>> 'mewtwo' in pokemon
   Solution: False
   >>> len(pokemon)
   Solution: 5
   >>> pokemon['ditto'] = pokemon['jolteon']
   >>> pokemon[('diglett', 'diglett', 'diglett')] = 51
   >>> pokemon[25] = 'pikachu'
   >>> pokemon
   Solution:
   >>> pokemon['mewtwo'] = pokemon['mew'] * 2
   >>> pokemon
   Solution:
   >>> pokemon[(['firetype', 'flying'])] = 146
   Solution: Error: unhashable type
   ```

Note that the last example demonstrates that dictionaries cannot use other mutable data structures as keys. However, dictionaries can be arbitrarily deep, meaning the values of a dictionary can be themselves dictionaries.
2. Write a function that takes in a sequence s and a function fn and returns a dictionary.

The values of the dictionary are lists of elements from s. Each element e in a list should be constructed such that fn(e) is the same for all elements in that list. Finally, the key for each value should be fn(e).

```python
def group_by(s, fn):
    grouped = {}
    for x in s:
        key = fn(x)
        if key in grouped:
            grouped[key].append(x)
        else:
            grouped[key] = [x]
    return grouped
```

Solution:
```python
grouped = {}
for x in s:
    key = fn(x)
    if key in grouped:
        grouped[key].append(x)
    else:
        grouped[key] = [x]
return grouped
```
